

Vectors and Components

Vectors have magnitude and direction. In order to add vectors together that are not on the x or y axis, we need to break them down into their x and y components, their horizontal and vertical components. Adding is, then, simple math.

Finding vector components requires the knowledge of basic trigonometry.

Basic trigonometry relationships:

$$\begin{aligned} \sin \theta &= \text{opposite/hypotenuse} \\ \cos \theta &= \text{adjacent/hypotenuse} \\ \tan \theta &= \text{opposite/adjacent} \end{aligned}$$

You will be given two of these quantities; find the rest from these formulas.

Ex. 1 If a vector's direction is $\theta = 40^\circ$ from the horizontal and the vertical component is 25 m/s, find the magnitude of the vector.

Step 1: Draw Diagram

Step 2: Assign variables

$$\begin{aligned} \text{vector} &= \text{hypotenuse} \\ 25 \text{ m/s} &= \text{opposite} \\ \theta &= 40^\circ \end{aligned}$$

Step 3: Equation

$$\sin \theta = \text{opp./hypo.}$$

Step 4: Solve

$$\begin{aligned} \sin 40^\circ &= (25 \text{ m/s})/\text{hypo.} \\ \text{hypo.} &= (25 \text{ m/s})/\sin 40^\circ \\ \text{hypo.} &= (25 \text{ m/s})/(.6428) \\ \text{hypo.} &= \mathbf{39 \text{ m/s}} \end{aligned}$$

Ex. 2 What is the horizontal component of a 30 N force applied 30° to the horizontal.

Step 1: Draw Diagram

Step 2: Assign variables

$$\begin{aligned} 30 \text{ N} &= \text{hypotenuse} \\ x &= \text{adjacent} \\ \theta &= 30^\circ \end{aligned}$$

Step 3: Equation

$$\cos \theta = \text{adj./hypo.}$$

Step 4: Solve

$$\begin{aligned} \cos 30^\circ &= x/(30 \text{ N}) \\ (30 \text{ N})(\cos 30^\circ) &= x \\ (30 \text{ N})(.866) &= x \\ x &= \mathbf{25.98 \text{ N}} \end{aligned}$$

Because you will find the vector components so often, it will be helpful to derive two component equations:

Vector Component Equations

$$\cos \theta = \text{adjacent/hypotenuse} \\ \mathbf{\text{adjacent} = \text{hypotenuse}(\cos \theta)}$$

$$\sin \theta = \text{opposite/hypotenuse} \\ \mathbf{\text{opposite} = \text{hypotenuse}(\sin \theta)}$$

Ex. 3 A person drives 20 miles north and 45 miles east. What is the angle of the resultant vector straight to their destination?

Step 1: Draw Diagram

Step 2: Assign variables

$$\begin{aligned} 20 \text{ mi} &= \text{opposite} \\ 45 \text{ mi} &= \text{adjacent} \\ \theta &= ? \end{aligned}$$

Step 3: Equation

$$\tan \theta = \text{opp./adj.}$$

Step 4: Solve

$$\begin{aligned} \tan \theta &= 20 \text{ mi}/45 \text{ mi} \\ \tan \theta &= .4444 \\ \theta &= \tan^{-1}(.4444) \\ \theta &= \mathbf{24^\circ} \end{aligned}$$

Calculator tip: for \tan^{-1} push (INV)tan or (2nd)tan

Ex. 4 A plane is flying 50 m/s and 60° up into the air. How much altitude will it gain in 6 seconds?

Step 1: Draw Diagram

Step 2: Assign variables

$$\begin{aligned} 50 \text{ m/s} &= \text{hypotenuse} \\ y &= \text{opposite} \\ \theta &= 60^\circ \end{aligned}$$

Step 3: Equation

$$\text{opp.} = \text{hypo}(\sin \theta)$$

Step 4: Solve

$$\begin{aligned} y &= \text{vector}(\sin \theta) \\ y &= (50 \text{ m/s})(\sin 60^\circ) \\ y &= (50 \text{ m/s})(.866) \\ y &= \mathbf{43.3 \text{ m/s}} \end{aligned}$$

Not the final answer: this is just the y-component of the speed. We must still find distance.

Hint: "Altitude" means "height above the ground." So you need the vertical component of the speed. Then you can find distance from speed and time.

Step 5: speed equation

$$\begin{aligned} \text{Vertical speed} &= 43.3 \text{ m/s} \\ v &= \Delta x/\Delta t \end{aligned}$$

Step 6: solve

$$\begin{aligned} 43.3 \text{ m/s} &= \Delta x/(6 \text{ sec}) \\ (6 \text{ sec})(43.3 \text{ m/sec}) &= \Delta x \\ \mathbf{259.8 \text{ m} = \Delta x} \end{aligned}$$
